Announcements

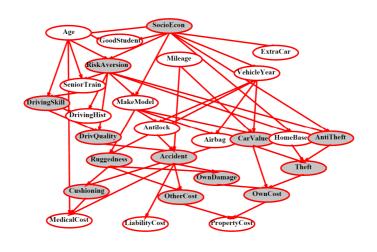

- Midterm
 - Next TUESDAY, 10/25, 5-8pm
 - Prep page is on the web (practice exams, etc)
 - Topical review sessions: see prep page
 - Overall review: in class Thursday
 - If you have a conflict, we should already know about it!
- Written 3
 - Due this Friday but fixes not due until NEXT Friday
- P1, P2, W1 in glookup

CS 188: Artificial Intelligence Fall 2011

Lecture 16: Bayes Nets IV 10/18/2011

Dan Klein - UC Berkeley

Approximate Inference

3

Approximate Inference

- Simulation has a name: sampling
- Sampling is a hot topic in machine learning, and it's really simple

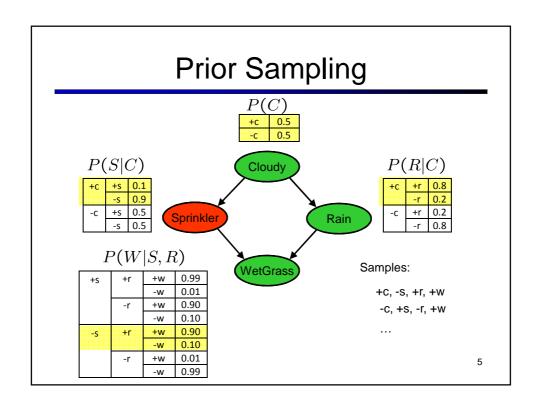

- Draw N samples from a sampling distribution S
- Compute an approximate posterior probability
- Show this converges to the true probability P

Why sample?

- Learning: get samples from a distribution you don't know
- Inference: getting a sample is faster than computing the right answer (e.g. with variable elimination)

Prior Sampling

This process generates samples with probability:

$$S_{PS}(x_1 \dots x_n) = \prod_{i=1}^n P(x_i | \mathsf{Parents}(X_i)) = P(x_1 \dots x_n)$$

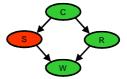

...i.e. the BN's joint probability

- Let the number of samples of an event be $N_{PS}(x_1 \dots x_n)$
- Then $\lim_{N\to\infty} \hat{P}(x_1,\ldots,x_n) = \lim_{N\to\infty} N_{PS}(x_1,\ldots,x_n)/N$ = $S_{PS}(x_1,\ldots,x_n)$ = $P(x_1\ldots x_n)$
- I.e., the sampling procedure is consistent

Example

• First: Get a bunch of samples from the BN:

$$+c$$
, $-s$, $+r$, $+w$

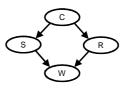

Example: we want to know P(W)

- We have counts <+w:4, -w:1>
- Normalize to get approximate P(W) = <+w:0.8, -w:0.2>
- This will get closer to the true distribution with more samples
- Can estimate anything else, too
- What about P(C| +w)? P(C| +r, +w)? P(C| -r, -w)?
- Fast: can use fewer samples if less time (what's the drawback?)

_

Rejection Sampling

- Let's say we want P(C)
 - No point keeping all samples around
 - Just tally counts of C as we go

- Let's say we want P(C| +s)
 - Same thing: tally C outcomes, but ignore (reject) samples which don't have S=+s
 - This is called rejection sampling
 - It is also consistent for conditional probabilities (i.e., correct in the limit)

Sampling Example

- There are 2 cups.
 - The first contains 1 penny and 1 quarter
 - The second contains 2 quarters
- Say I pick a cup uniformly at random, then pick a coin randomly from that cup. It's a quarter (yes!). What is the probability that the other coin in that cup is also a quarter?

Likelihood Weighting

- Problem with rejection sampling:
 - If evidence is unlikely, you reject a lot of samples
 - You don't exploit your evidence as you sample
 - Consider P(B|+a)

-b, -a -b, -a

Burglary Alarm -b, -a

- +b, +a
- Idea: fix evidence variables and sample the rest

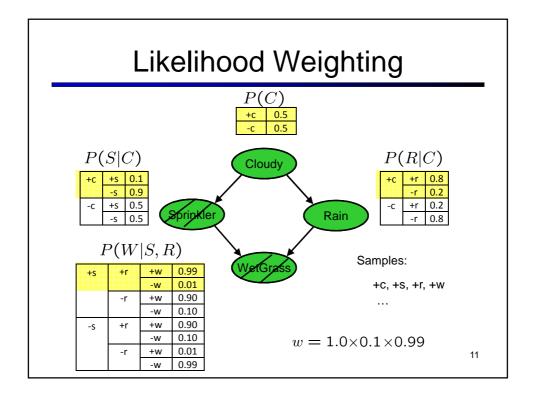

-b +a

-b, -a

-b, +a -b, +a -b, +a

- Problem: sample distribution not consistent!
- +b, +a
- Solution: weight by probability of evidence given parents

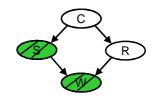

Likelihood Weighting

Sampling distribution if z sampled and e fixed evidence

$$S_{WS}(\mathbf{z}, \mathbf{e}) = \prod_{i=1}^{l} P(z_i | \mathsf{Parents}(Z_i))$$

Now, samples have weights

$$w(\mathbf{z}, \mathbf{e}) = \prod_{i=1}^{m} P(e_i | \mathsf{Parents}(E_i))$$

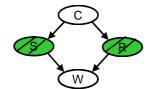

Together, weighted sampling distribution is consistent

$$egin{aligned} S_{ ext{WS}}(z,e) \cdot w(z,e) &= \prod_{i=1}^{l} P(z_i | ext{Parents}(z_i)) \prod_{i=1}^{m} P(e_i | ext{Parents}(e_i)) \\ &= P(ext{z}, ext{e}) \end{aligned}$$

Likelihood Weighting

- Likelihood weighting is good
 - We have taken evidence into account as we generate the sample
 - E.g. here, W's value will get picked based on the evidence values of S, R
 - More of our samples will reflect the state of the world suggested by the evidence
- Likelihood weighting doesn't solve all our problems
 - Evidence influences the choice of downstream variables, but not upstream ones (C isn't more likely to get a value matching the evidence)
- We would like to consider evidence when we sample every variable

13

Markov Chain Monte Carlo*

- Idea: instead of sampling from scratch, create samples that are each like the last one.
- Procedure: resample one variable at a time, conditioned on all the rest, but keep evidence fixed. E.g., for P(B|+c):

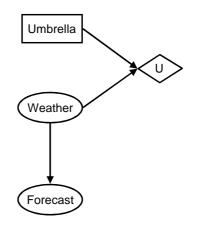

- Properties: Now samples are not independent (in fact they're nearly identical), but sample averages are still consistent estimators!
- What's the point: both upstream and downstream variables condition on evidence.

Decision Networks

- MEU: choose the action which maximizes the expected utility given the evidence
- Can directly operationalize this with decision networks
 - Bayes nets with nodes for utility and actions
 - Lets us calculate the expected utility for each action
- New node types:
 - Chance nodes (just like BNs)
 - Actions (rectangles, cannot have parents, act as observed evidence)
 - Utility node (diamond, depends on action and chance nodes)

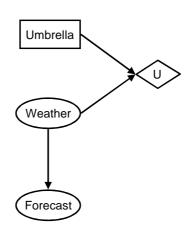

[DEMO: Ghostbusters]

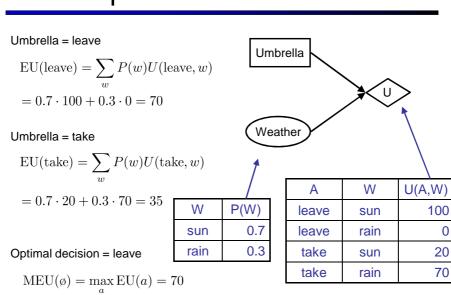

15

Decision Networks

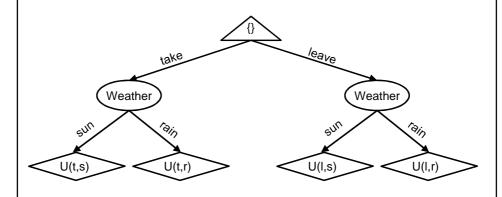

- Action selection:
 - Instantiate all evidence
 - Set action node(s) each possible way
 - Calculate posterior for all parents of utility node, given the evidence
 - Calculate expected utility for each action
 - Choose maximizing action

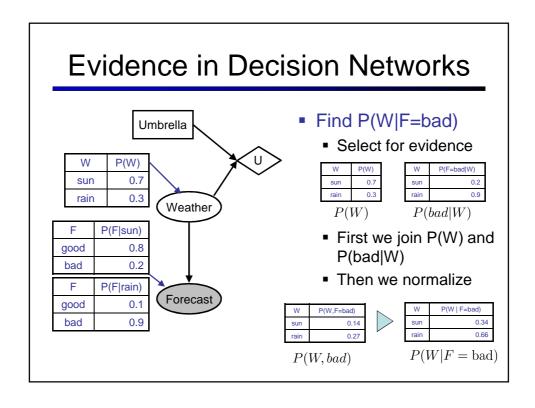

Example: Decision Networks

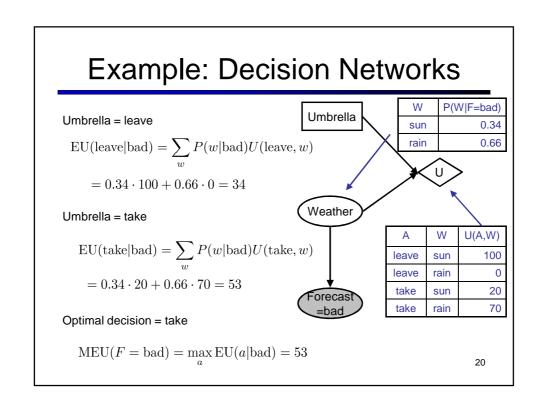

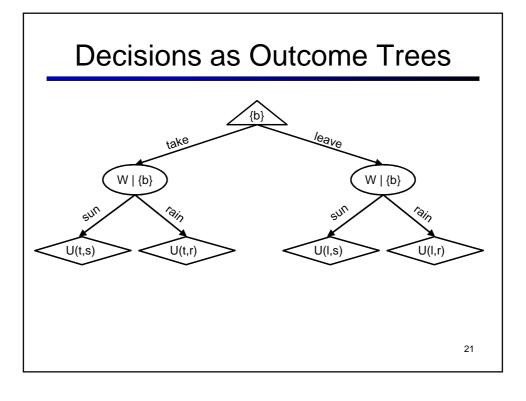

- Almost exactly like expectimax / MDPs
- What's changed?

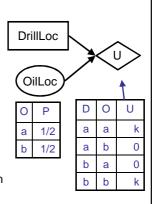

Value of Information

- Idea: compute value of acquiring evidence
 - Can be done directly from decision network
- Example: buying oil drilling rights
 - Two blocks A and B, exactly one has oil, worth k
 - You can drill in one location
 - Prior probabilities 0.5 each, & mutually exclusive
 - Drilling in either A or B has EU = k/2, MEU = k/2
- Question: what's the value of information of O?
 - Value of knowing which of A or B has oil
 - Value is expected gain in MEU from new info
 - Survey may say "oil in a" or "oil in b," prob 0.5 each
 - If we know OilLoc, MEU is k (either way)
 - Gain in MEU from knowing OilLoc?
 - VPI(OilLoc) = k/2
 - Fair price of information: k/2

Value of Information

Assume we have evidence E=e. Value if we act now:

$$\mathsf{MEU}(e) = \max_{a} \sum_{s} P(s|e) \ U(s,a)$$

Assume we see that E' = e'. Value if we act then:

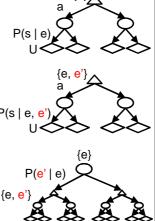

$$MEU(e, e') = \max_{a} \sum_{s} P(s|e, e') U(s, a)$$

- BUT E' is a random variable whose value is unknown, so we don't know what e' will be
- Expected value if E' is revealed and then we act:

$$\mathsf{MEU}(e,E') = \sum_{e'} P(e'|e) \mathsf{MEU}(e,e')$$

Value of information: how much MEU goes up by revealing E' first then acting, over acting now:

$$VPI(E'|e) = MEU(e, E') - MEU(e)$$

VPI Example: Weather

MEU with no evidence

$$MEU(\emptyset) = \max_{a} EU(a) = 70$$

MEU if forecast is bad

$$MEU(F = bad) = \max_{a} EU(a|bad) = 53$$

MEU if forecast is good

$$MEU(F = good) = \max_{a} EU(a|good) = 95$$

Forecast distribution

F	P(F)	
good	0.59	
bad	0.41	

$$0.59 \cdot (95) + 0.41 \cdot (53) - 70$$

Umbrella

Weather

Forecast

leave

leave

$$\begin{array}{c|c} \hline \text{good} & 0.59 \\ \hline \text{bad} & 0.41 \\ \hline \end{array} \begin{array}{c} 0.59 \cdot (95) + 0.41 \cdot (55) = 70 \\ \hline 77.8 - 70 = 7.8 \\ \hline \end{array}$$

$$\text{VPI}(E|e') = \left(\sum_{e'} P(e'|e) \text{MEU}(e,e')\right) - \text{MEU}(e)$$

100

VPI Properties

Nonnegative

$$\forall E', e : \mathsf{VPI}(E'|e) \geq 0$$

Nonadditive – consider, e.g., obtaining E_i twice

$$VPI(E_i, E_k|e) \neq VPI(E_i|e) + VPI(E_k|e)$$

Order-independent

$$VPI(E_j, E_k|e) = VPI(E_j|e) + VPI(E_k|e, E_j)$$
$$= VPI(E_k|e) + VPI(E_j|e, E_k)$$

Quick VPI Questions

- The soup of the day is either clam chowder or split pea, but you wouldn't order either one. What's the value of knowing which it is?
- There are two kinds of plastic forks at a picnic. One kind is slightly sturdier. What's the value of knowing which?
- You're playing the lottery. The prize will be \$0 or \$100. You can play any number between 1 and 100 (chance of winning is 1%). What is the value of knowing the winning number?
